How Could Carbon Capture and Storage Work for Refineries?

***Wilfried Maas, Shell
Member of CONCAWE CCS Ad Hoc Group***

**9th CONCAWE Symposium
14-15th March 2011**

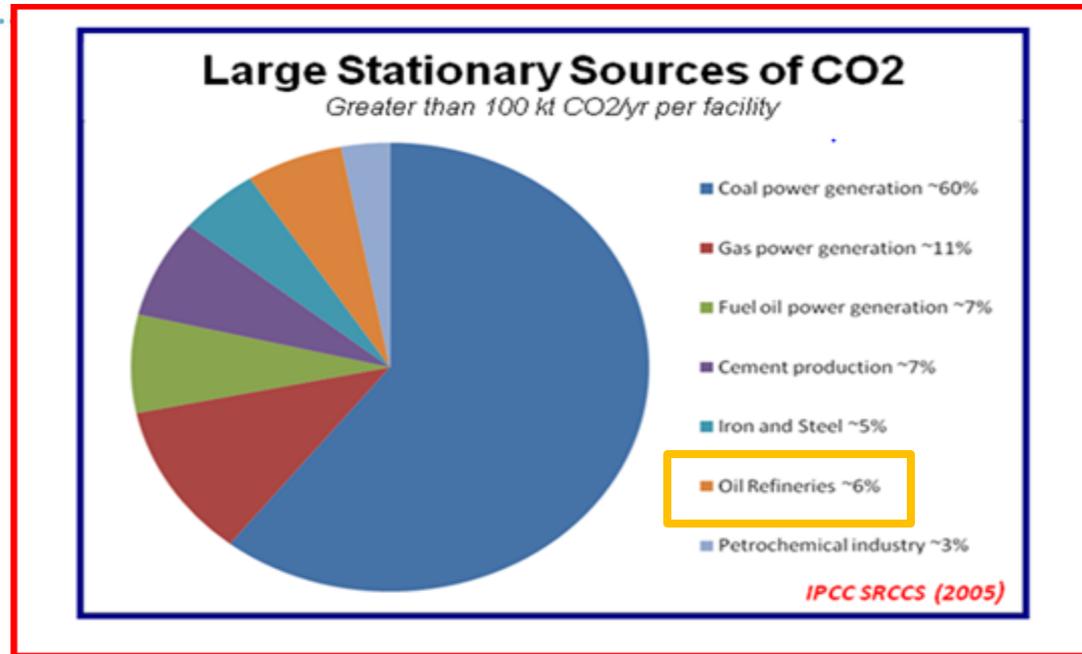

- ▶ Climate change is a challenge for governments, industry and consumers alike
- ▶ Cancun consensus: need to keep global temperature rise below 2°C
- ▶ Different scenarios target deep CO₂ reductions: 80 % CO₂ reduction by 2050 (a.o. IEA 450 scenario and blue map)
- ▶ Regulators target large emission sectors

- ▶ Power sector
 - ▶ Coal
 - ▶ Gas & fuel oil
- ▶ Industry sector
 - ▶ Cement
 - ▶ Iron and steel
 - ▶ Refining
 - ▶ Petrochemicals
- ▶ EU Refinery emissions could grow from 144 to 226 Mt CO₂/a

- ▶ Efficiency and fuel/feedstock switching are early responses for energy-intensive industries
- ▶ Refiners have taken actions with offering CO₂ (from POX) for food, greenhouses and CCS
- ▶ For deeper decarbonisation CCS is the only option
- ▶ The IEA CCS roadmap shows an ambitious pathway
 - ▶ CCS contributions mainly from power
 - ▶ Significant contributions from industrial sector

Source: CONCAWE internal study

- ▶ Refineries have multiple emission sources
- ▶ Large differences between refinery types and variations between individual refineries and locations
- ▶ Emissions (and number of sources) increasing with complexity

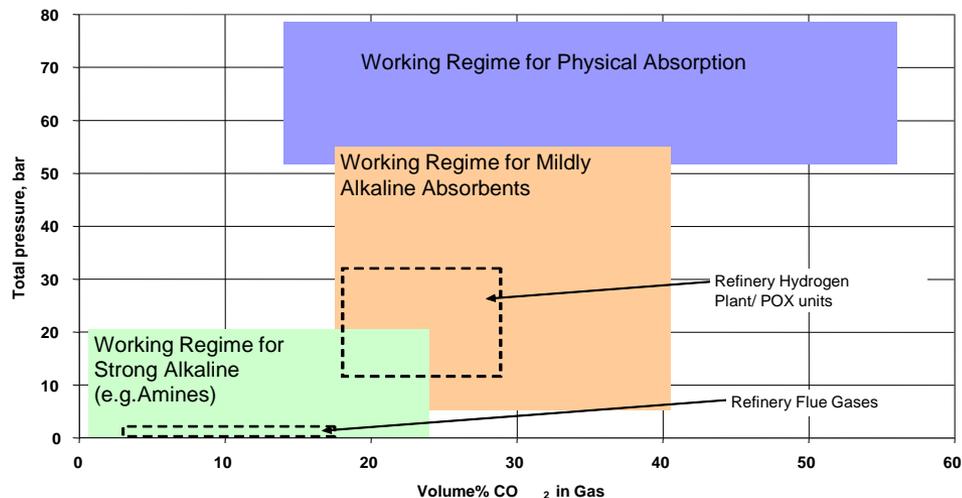

Reproduction permitted with due acknowledgement

- ▶ CO₂ Capture from most refinery sources is technically feasible
 - ▶ Though scale up and demonstration is needed
- ▶ Different Capture technologies
 - ▶ Post combustion
 - ▶ Pre combustion
 - ▶ Oxyfuel firing
 - ▶ Amine based capture technologies are known to refineries
- ▶ Different CO₂ concentrations and pressures at refinery
- ▶ Cost trade-off between options:
 - ▶ maximisation of CO₂ concentration of certain sources (e.g. oxyfuel) vs. simple large scale capture at lower CO₂ concentration
- ▶ Physical constraints for retrofits (e.g. plot space limitations)
 - ▶ May drive technology choice
 - ▶ May limit final capture rate
 - ▶ Will add to costs

concaawe CO₂ Capture needs energy -> "parasitic" CO₂

- ▶ CO₂ Capture units need power for CO₂ compression and heat for capture solvent regeneration
- ▶ For refineries with balanced utilities power and heat need to be generated by an additional utilities block
 - ▶ Of which the CO₂ emissions (15% to 30% of total) also need to be captured
 - ▶ CO₂ avoided < CO₂ captured
 - ▶ Which has a "roll-up" effect
 - ▶ Incremental CO₂ from utilities requires more energy to capture, which requires more energy production by utilities, etc...
 - ▶ Which increases the cost (Opex and Capex) of capture

Source: CONCAWE internal study

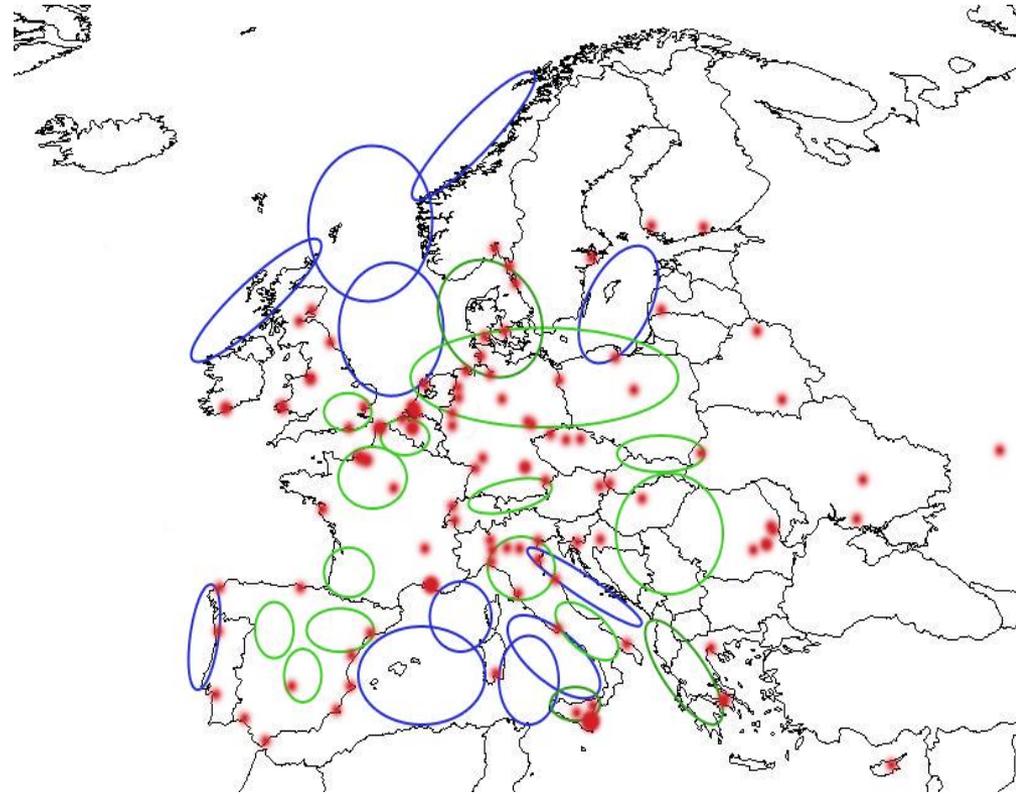

- ▶ Refinery Cost of CCS per ton CO₂ avoided will be significantly higher than the 40-60 Euro per ton CO₂, quoted for coal power and current ETS market prices:
 - ▶ Connecting all the distributed sources (instead of one source)
 - ▶ E.g. extensive ducts with fans to capture unit
 - ▶ Capex for sub-optimal size CCS utilities plant (instead of shared utilities)
 - ▶ Of which the emissions need to be captured too
 - ▶ Opex with fuel for capture plant at Natural Gas value (instead of coal)
 - ▶ Less economy of scale (1-2 vs 5 Mt/a)
 - ▶ Brownfield integration impact with e.g. extension of shut down periods
 - ▶ Residual lifetime of refinery to be taken into account
- ▶ Refinery specifics may result in large differences in CCS costs between refineries
 - ▶ Specifically between deep conversion (complex) and hydroskimming (simple)
- ▶ Cost to apply CCS at a refinery will add significantly to overall refinery CAPEX and operating costs
 - ▶ The impact on margins needs to be clarified, along with how these costs can be transferred
- ▶ Significant cost uncertainties since the technology has not been built to similar scale in a refinery application.
- ▶ Cost of transport and storage to be included (<15-20% of total CCS cost)
- ▶ *Watch this space for the CONCAWE CCS ad hoc workgroup to deliver their report*

- ▶ The refinery CO₂ sources need to be matched with CO₂ Storage sites
- ▶ Depleted Oil and Gas fields
 - ▶ Known, limited volume
- ▶ Deep Saline Aquifers
 - ▶ Larger potential volume but needs exploration
- ▶ Onshore and Offshore
 - ▶ Offshore at higher costs
- ▶ Sharing of storage sites with different industries will yield scale advantage

Location of EU Refineries and Potential CO₂ Storage Areas

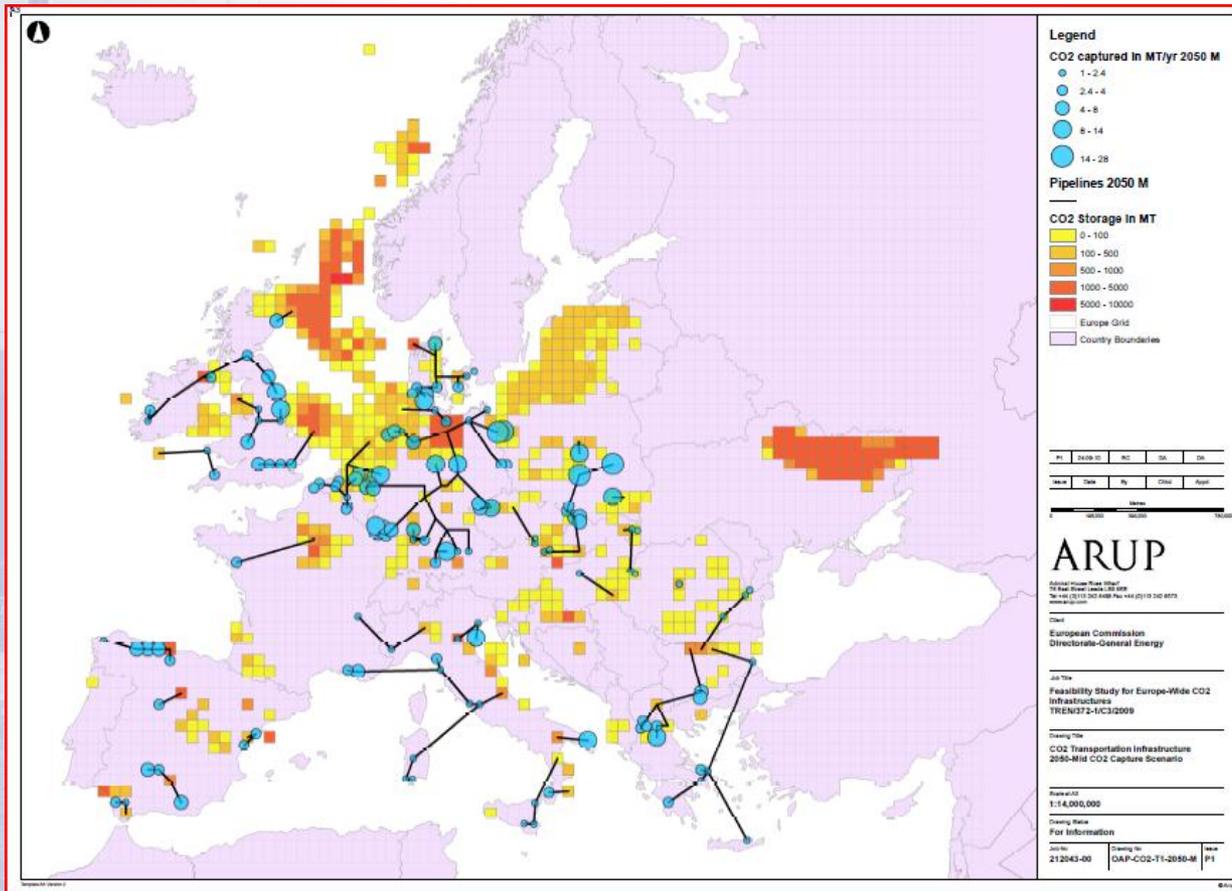

Source: The European Technology Platform for Zero Emission Fossil Fuel Power Plants (ZEP)

Legend: Red dots are refineries, blue and green bounded areas are potential offshore and onshore storage areas

Reproduction permitted with due acknowledgement

- ▶ CO₂ needs to be transported to storage locations by pipelines (or ships)
- ▶ Shared transport networks between capture facilities, for scale advantage

- ▶ CCS is technically feasible to reduce refinery CO₂ emissions
 - ▶ But needs scale up and demonstration
- ▶ Refinery retrofit CCS will be complex and expensive to implement
 - ▶ Specifically when compared with CCS in new-build power plants
- ▶ There are significant uncertainties with CCS cost estimates, since the technology has not been built to similar scale previously.
- ▶ Cost of CCS per ton CO₂ avoided in refining will be significantly higher than the current ETS CO₂ market prices and the 40-60 Euro per ton CO₂ cost quoted for coal power
- ▶ For refiners deep CO₂ reduction (greater than 90%) may be physically impossible or impractical due to multiple source types and capture efficiency limits
- ▶ Piggybacking on a larger CO₂ transport network will be crucial
- ▶ Refiners need to progress the options to potentially deploy CCS in response to alternative approaches to CO₂ market mechanisms
 - ▶ Learn from demonstrations
